Weather

Anticipating Weather (In 1hr, 1 day, at 1km) Minimizes Reserve Cost

Objective 1: Uncertainty quantification in weather forecast: A test case with real data

- Importance in Energy Systems Management
 - Weather influences both energy supply (wind/solar/thermal) and demand
 - Accurate weather/climate forecast leads to an efficient proactive resource management (reduces needed reserves and cost, though not consumption directly).
- Weather forecasting at the renewable energy (RE) system scale (1km) is a grand challenge:
 - very large-system, difficult to simulate
 - Chaotic,
 - incomplete/missing physics
 - unknown initial conditions, uncertain forcings
 - Lack of information makes deterministic prediction impossible, we must quantify and compute uncertainty in weather forecast (i.e. its probability distribution).
- **Objective 1: Is there hope of predicting the probability **distribution** of weather at RE scale **operationally** ? (24 hour ahead in 1 hour at 1 km)?**

Objective 2: What is the economic impact of using weather (and demand/pricing) forecast in energy management

- The impact strongly depends on the decision system and of the way it accounts for risk.
- We posit the decision problem under uncertainty as a stochastic programming problem.
- Note that we do not expect to reduce consumption, (that is design, not management), but we expect to be able to reduce cost, and implicitly
 - Reduce the risk of not meeting demand
 - Reduce the peak requirements on power grid and this increase resilience by optimally answering to the appropriate incentives (such as electricity pricing).
- Question 2: For realistic Independent System Operator Problems, Building Systems, and Photovoltaic Systems, what are the expected cost reductions?

Forecast and Uncertainty

Uncertainty in dynamical systems: 1. Data

- Assume a time-discretized process with imperfect initial state and forcing information and noisy measurements.

The dynamic model is depicted as for $k = 0, \dots, K$

$$\mathbf{x}_k^{in} = M(\mathbf{x}_{k-1}^{in}) + W_k, \quad (1)$$

$$\mathbf{z}_k^{obs} = H(\mathbf{x}_k^{in}) + V_k, \quad (2)$$

where

$$W_k \approx N(\bar{\mathbf{x}}_k, Q_k^{-1})$$

and

$$V_k \approx N(\mathbf{0}, R_k^{-1}).$$

We want find $D(\mathbf{x}_0^{in}, \dots, \mathbf{x}_K^{in})$'s mean and variance.

Uncertainty in dynamical systems: 2. the posterior.

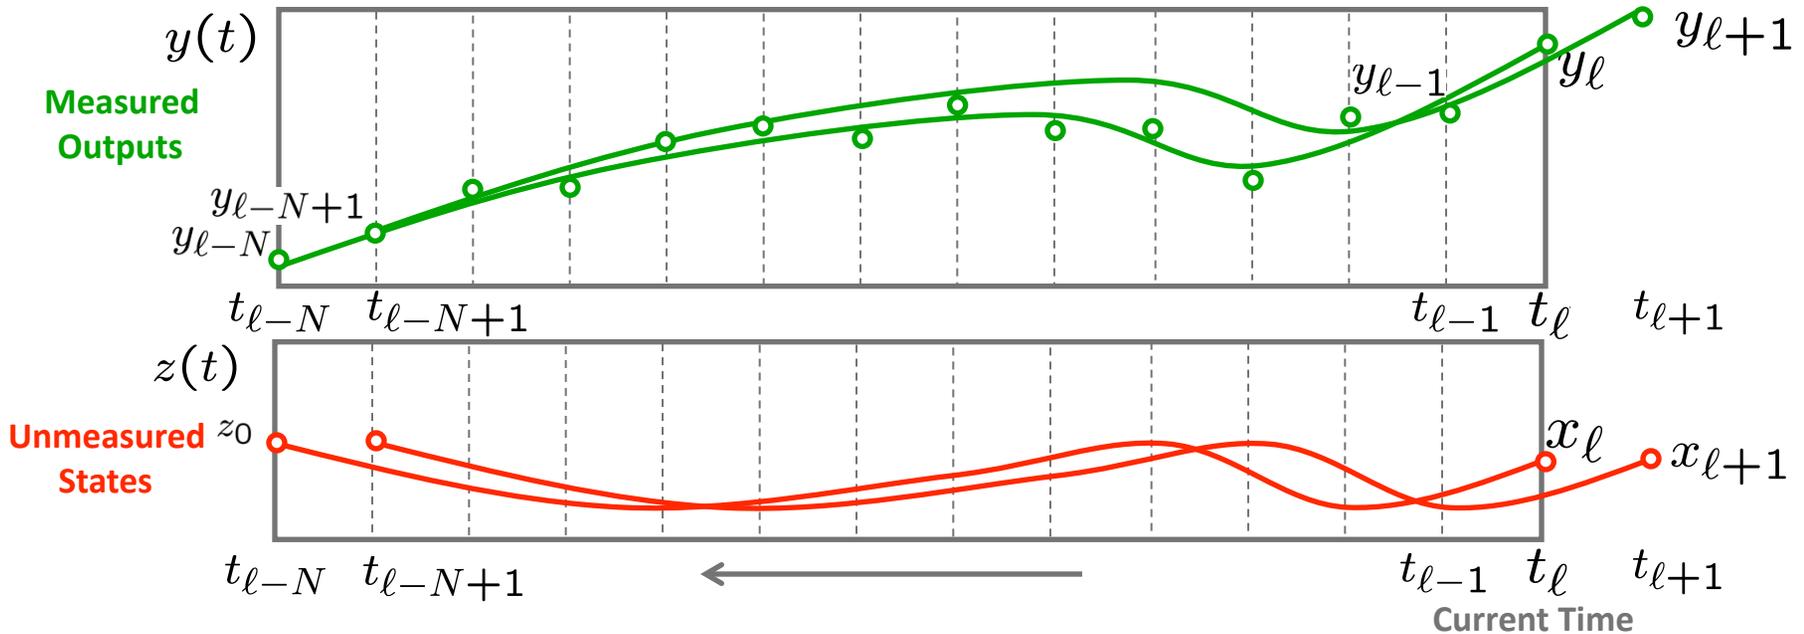

- Under the typical 4D Var assumptions (normality of noise and input and independence) we can write down the posterior ...

$$P(\mathbf{x}_k^{in}, \mathbf{x}_{k-1}^{in}, \dots, \mathbf{x}_0^{in} | z_0^{obs}, z_1^{obs}, z_2^{obs}, \dots, z_k^{obs}) = C_k \tilde{C}_k \frac{\exp\left(-\frac{1}{2} f(\mathbf{X}^{in}, \mathbf{Z}^{obs})\right)}{P(\mathbf{Z}^{obs})}.$$

$$f(\mathbf{X}^{in}, \mathbf{Z}^{obs}) = \sum_{i=0}^k (\mathbf{x}_i^{in} - \bar{\mathbf{x}}_i - \tilde{\mathbf{y}}(t_{i-1}, \mathbf{x}_{i-1}^{in}))^T Q_i^{-1} (\mathbf{x}_i^{in} - \bar{\mathbf{x}}_i - \tilde{\mathbf{y}}(t_{i-1}, \mathbf{x}_{i-1}^{in})) \\ + \sum_{i=0}^k (z_i^{obs} - h_i(\tilde{\mathbf{y}}^\perp(t_i, \mathbf{x}_i^{in})))^T R_i^{-1} (z_i^{obs} - h_i(\tilde{\mathbf{y}}^\perp(t_i, \mathbf{x}_i^{in})))$$

- A very difficult distribution to sample from.
- Solution: first, find the best estimate of the state.
- Then, approximate the prior covariance by an ergodic/Gaussian Process method.

Step 1: Moving Horizon Best State Estimation

$$\min_{p(t), z_0} \sum (y(t_k) - \underline{y_{l-k+N}})^T \mathbf{V}_y^{-1} (y(t_k) - \underline{y_{l-k+N}})$$

$$\min_{p(t), z_0} \sum (y(t_k) - y_{l-k+N+1})^T \mathbf{V}_y^{-1} (y(t_k) - y_{l-k+N+1})$$

WRF Model

$$\frac{dz}{dt} = \mathbf{f}(z(t), p(t), u(t))$$

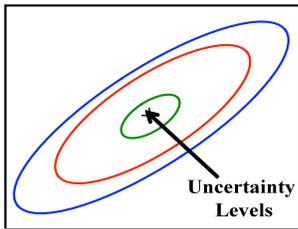

$$y(t) = \mathbf{g}(z(t), p(t), u(t))$$

$$z(0) = z_0 \text{ Uncertain}$$

$$\frac{dz}{dt} = \mathbf{f}(z(t), p(t), u(t))$$

$$y(t) = \mathbf{g}(z(t), p(t), u(t))$$

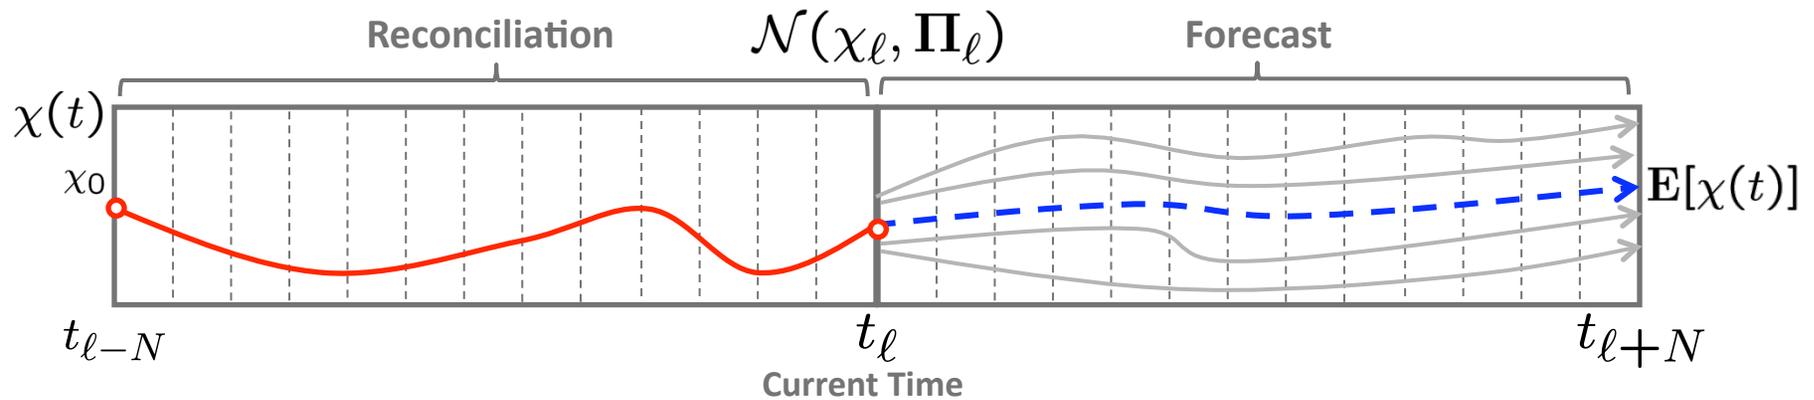

$$z(0) = z_0$$

$$\mathbf{\Pi}_l \rightarrow 0$$

Uncertainty in Current State x_l
Needed To Quantify Future Forecast

Step 2: Estimate the prior covariance matrix.

- Use some form of an ergodic hypothesis. Take $d_{ij} \in \mathbb{R}^{N \times (2 \times 30 \text{days})}$,

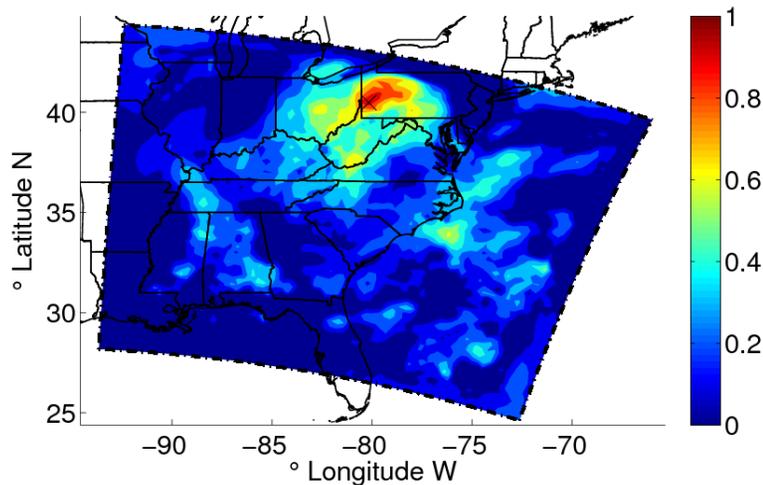

$$\mathbf{V}_{ik} \approx \mathbf{d} \mathbf{d}^T = \sum_j d_{ij} d_{kj}^T = \epsilon_i \cdot \epsilon_k = \begin{bmatrix} \epsilon_0 \cdot \epsilon_0 & \epsilon_1 \cdot \epsilon_0 & \cdots & \epsilon_n \cdot \epsilon_0 \\ \epsilon_0 \cdot \epsilon_1 & \epsilon_1 \cdot \epsilon_1 & \cdots & \epsilon_n \cdot \epsilon_1 \\ \cdots & \cdots & \cdots & \cdots \\ \epsilon_0 \cdot \epsilon_n & \epsilon_1 \cdot \epsilon_n & \cdots & \epsilon_n \cdot \epsilon_n \end{bmatrix}, \quad \mathbf{C}_{ik} = \frac{\epsilon_i \cdot \epsilon_k}{|\epsilon_i| |\epsilon_k|}.$$

- “Guess” the diagonal of the variance matrix

Step 2 b: Fit to a Gaussian Process.

Covariance Matrix is Huge and low rank ($10^6 \times 10^6$) But ...

- Spatial Correlations Decay Exponentially *Constantinescu, et.al., 2007*
- Covariance Can be Approximated Using Gaussian Kernels *Zavala, Constantinescu & A, 2009*

$$\Pi_{:,i,j} = \exp \left(-\frac{(x_j - x_i)^2 + (y_j - y_i)^2}{L_H^2} - \frac{(z_j - z_i)^2}{L_V^2} \right)$$

Ensemble Forecast Approach

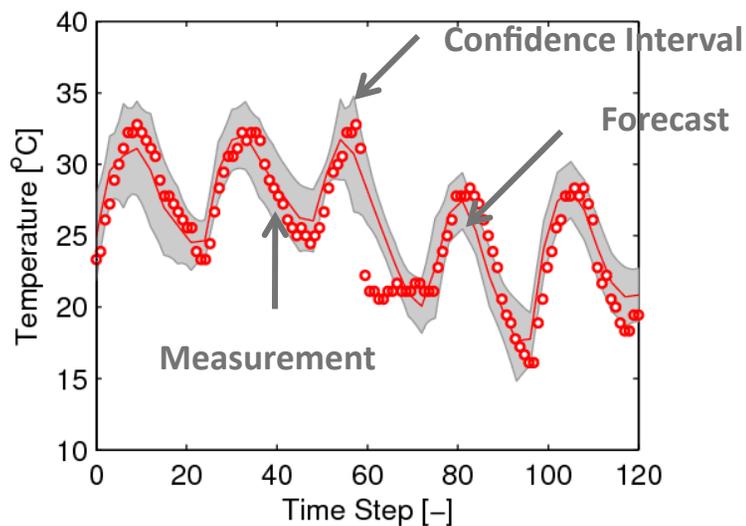

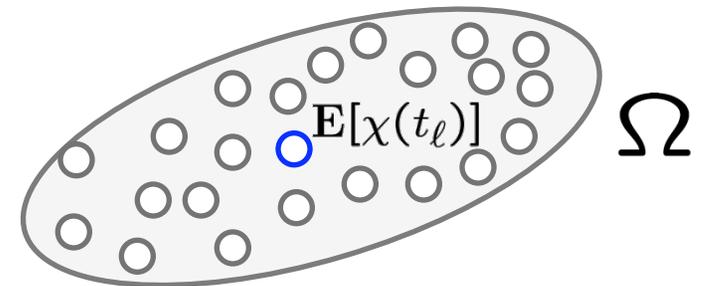

Ensemble Forecast Approach – Use WRF as Black-Box

Sample Prior and Propagate Samples of Posterior Through Model

$$Y_{[i,j]} := \chi_i(t_{\ell+j}) = \underbrace{\mathcal{M}(\mathcal{M}(\dots\mathcal{M}(\chi_i(t_{\ell}))))}_{j \text{ times}}$$

$$E[Y] \approx \bar{Y} := \frac{1}{NS} \sum_{i=1}^{NS} Y_{[i,:]}$$

$$V \approx \frac{1}{NS - 1} \sum_{i=1}^{NS} (Y_{[i,:]} - \bar{Y})(Y_{[i,:]} - \bar{Y})^T$$

Hours (August 1st-5th)

Validation Results, Pittsburgh Area 2006

5 Day Forecast and +/- 3σ Intervals

Building applications

Uncertainty quantification and forecast using WRF

- WRF model: $x^{t_F} = \mathcal{M}_{t_0 \rightarrow t_F}(x^{t_0})$
- Uncertainties in the initial conditions: $x_i^{t_0} = x_{\text{NARR}} + \mathbf{L}\xi_i$

$$\xi_i \sim \mathcal{N}(0, I), \quad i \in [1, N_S], \quad \mathbf{L}\mathbf{L}^T = \mathbf{P}, \quad \mathbf{C}_{ij} = \frac{\mathbf{P}_{ij}}{\sqrt{\mathbf{P}_{ii}\mathbf{P}_{jj}}}$$

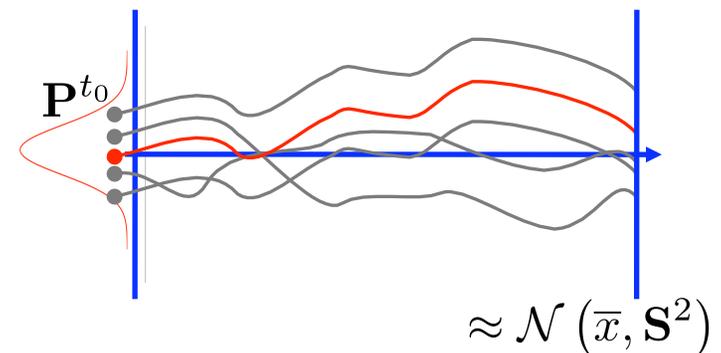

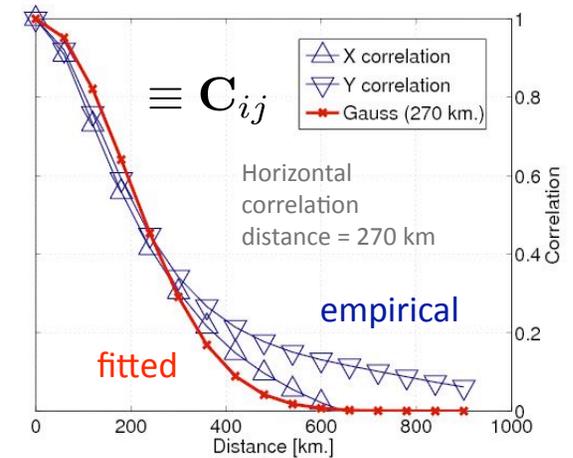

- Evolution of uncertainties through WRF:

$$x_i^{t_F} = \mathcal{M}_{t_0 \rightarrow t_F}(x_i^{t_0}) + \eta_i(t)$$

$$x_i^{t_0} \sim \mathcal{N}(x_{\text{NARR}}, \mathbf{P}^{t_0}), \quad \eta_i \sim \mathcal{N}(0, \mathbf{Q}), \quad i \in [1, N_S]$$

- Uncertainty at the final time: $x_i^{t_F} \sim \mathcal{N}(\bar{x}, \mathbf{S}^2)$

$$\bar{x} = \frac{1}{N_S} \sum_{i=1}^{N_S} x_i \quad \mathbf{S}^2 = \frac{1}{N_S - 1} \sum_{i=1}^{N_S} (x_i - \bar{x})(x_i - \bar{x})^T$$

Closed loop simulation using WRF

- 24-hour simulation window – restart from assimilated solution (NARR) every 12 hours

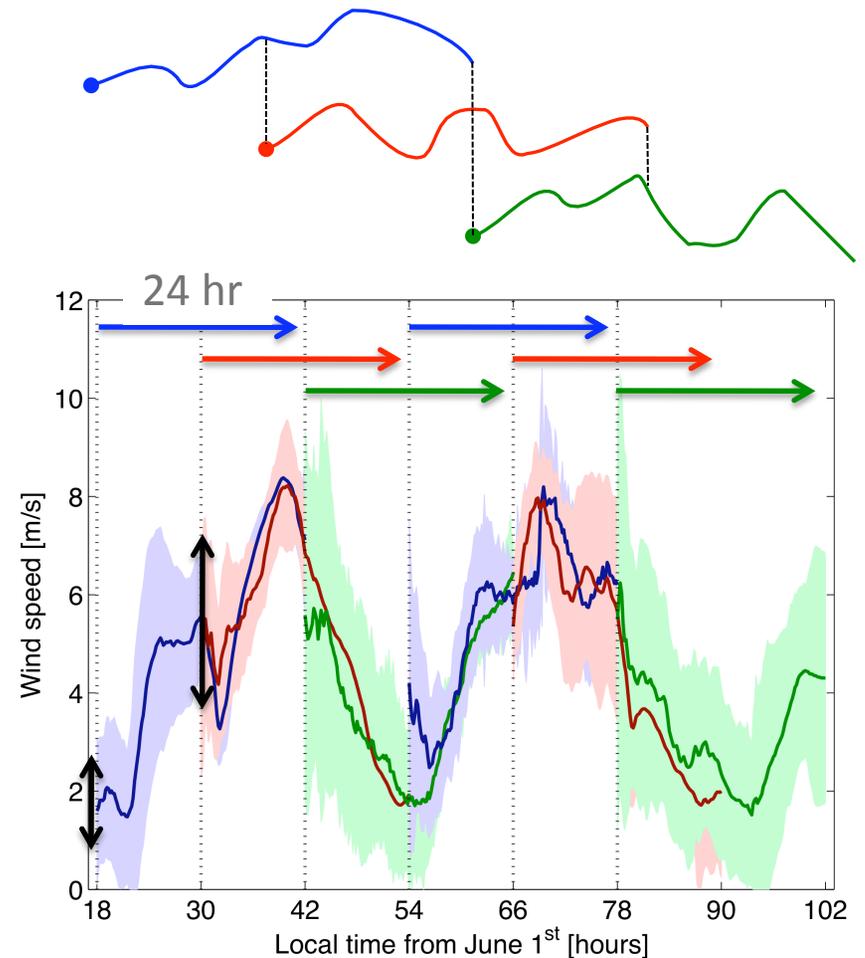

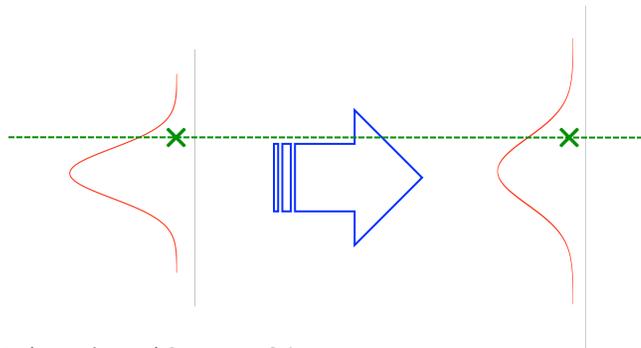

- Restart ensemble with adjusted spread based on error estimates:

$$x_i \leftarrow \bar{x} + \gamma (x_i - \bar{x}), \quad i \in [1, N_S]$$

$$\gamma = \max(1, \min(\gamma_\sigma, 4))$$

$$\gamma_\sigma = \text{mean}_{U,V,T|k=1\dots 5} \left(\frac{|x_{\text{NARR}} - \bar{x}|}{\sigma} \right)$$

- Error is underestimated: increase uncertainty

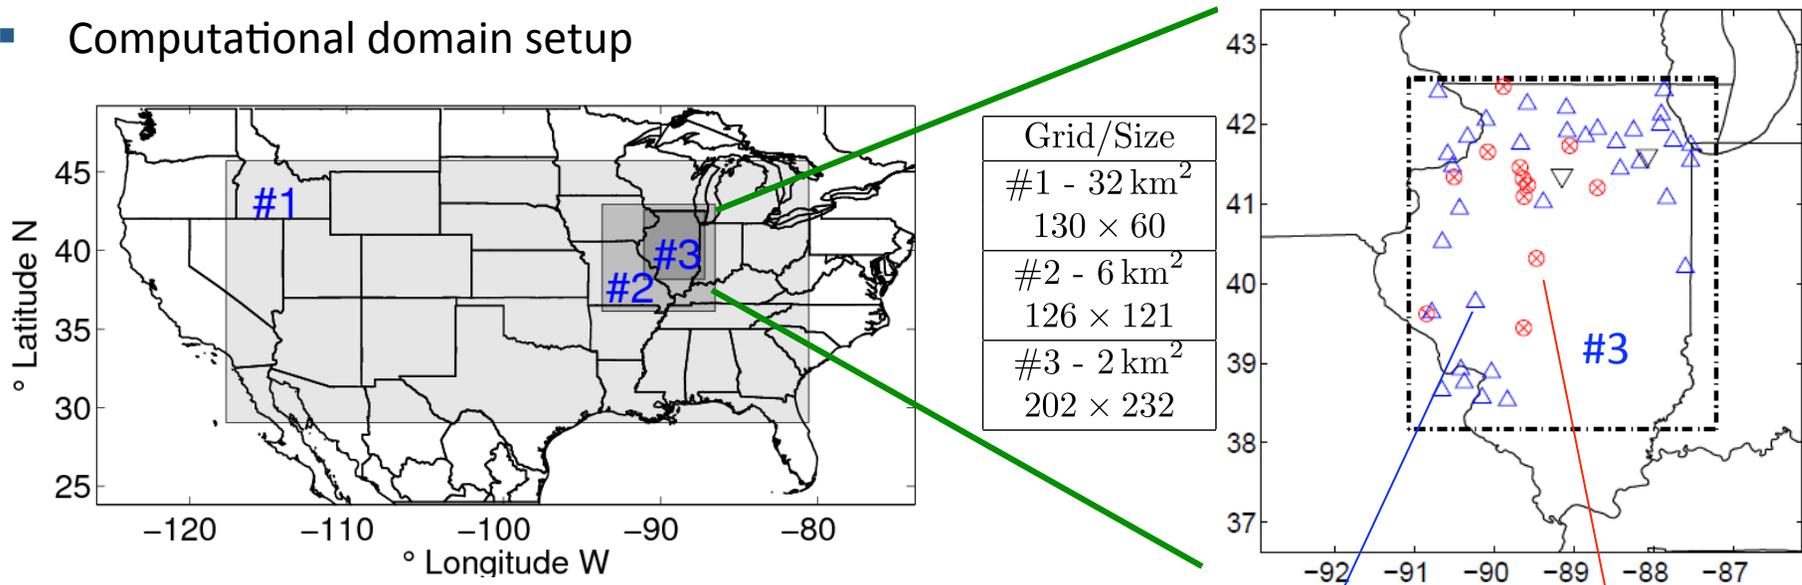

Implementation and Estimation of Necessary Computational Resources

Ensemble forecast and uncertainty quantification with WRF on Jazz

- Computational domain setup

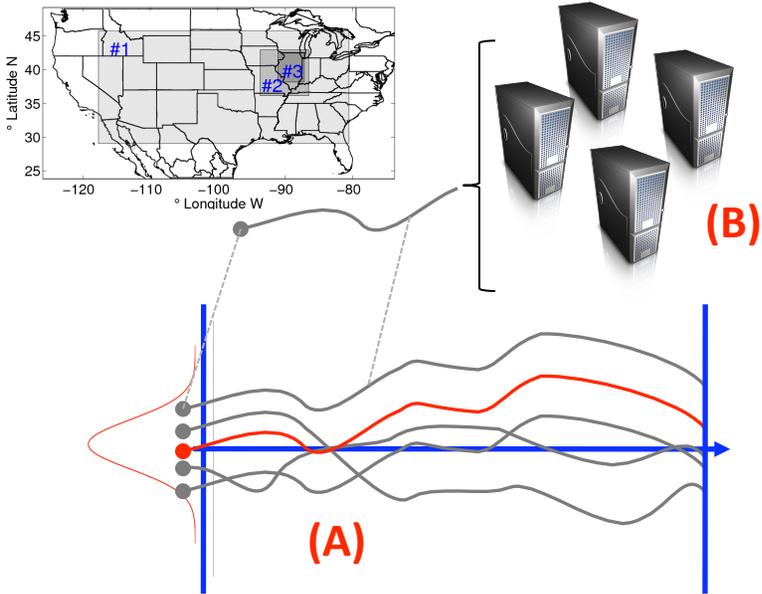

- Jazz:** 350 nodes; Intel Pentium IV Xeon@ 2.4GHz; 1 or 2 Gb RAM per node; Myrinet 2000 @ 0.25 GB/s, 6-8 μsec latency

- 24 hours** [simulation time] in **one hour** [real time] on Jazz with 30 members on **500 processors**;

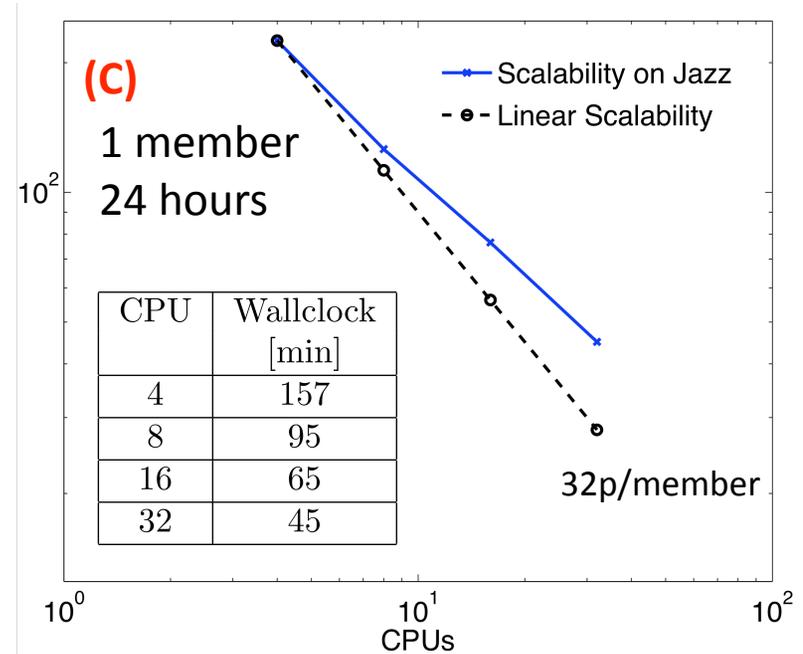

WRF scalability on Jazz

- Two-level parallelization scheme – very scalable: **(A)** realizations are independent, **(B)** each is parallelized, and **(C)** explicit

	Grid	Size
US:	#1 - 32 km ²	130 × 60
	#2 - 6 km ²	126 × 121
Illinois:	#3 - 2 km ²	202 × 232

- 24 hours [simulation time] -> one hour [real time] on Jazz with 30 members; [2 km]; (almost) linear scalability with area **(C)**

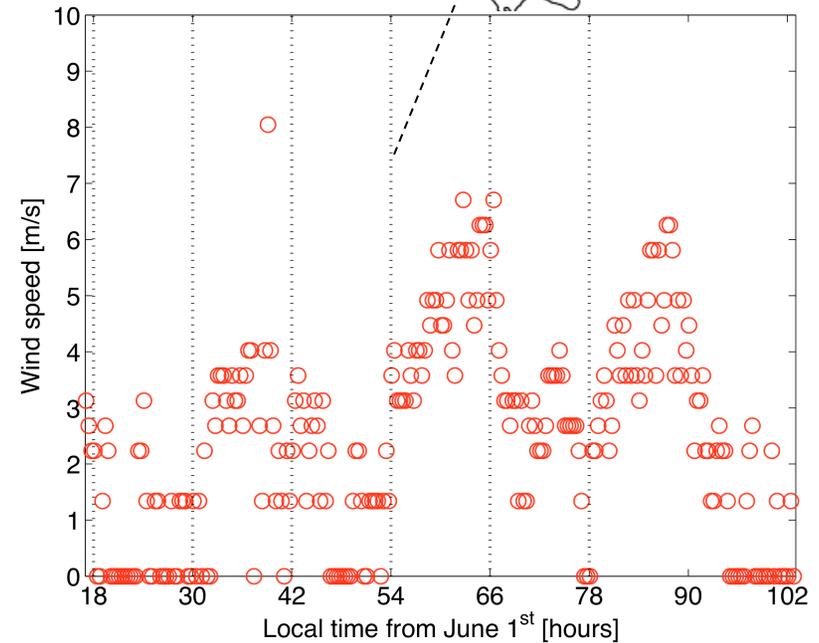

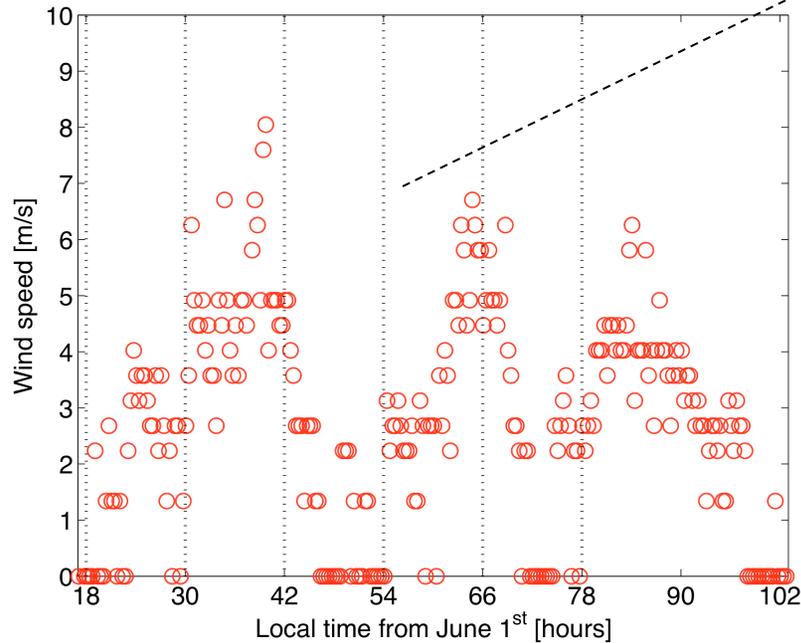

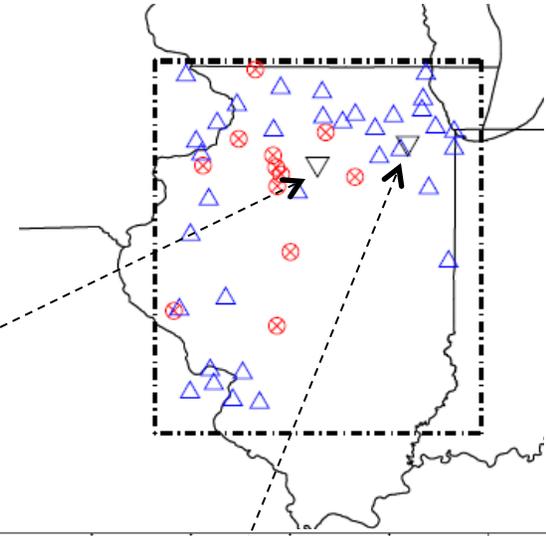

- ✓ Illinois [2km]: 500 processors
- US [2 km]: ~50,000 processors
- US [1 km]: ~400,000 processors

Validation of the results

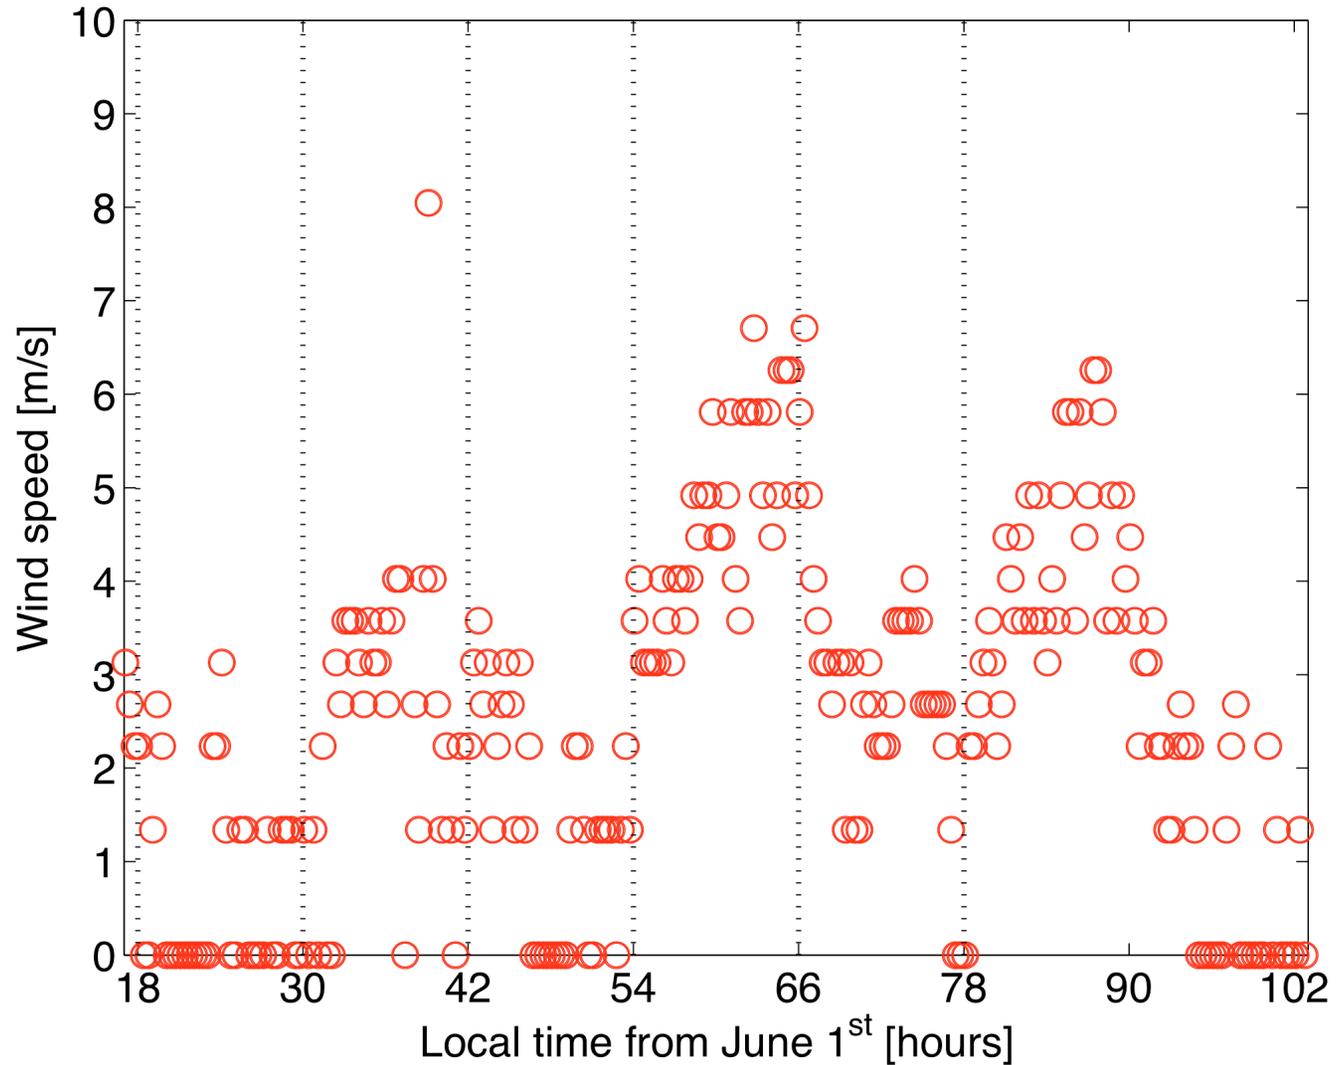

Wind power measurements and windmill locations

- Wind turbine locations and weather stations locations in Illinois:
- Real wind and temperature measurements for hindcast (June 2006) ~every 20 min.
- Real wind power measurements for Chicago and Peru, IL:

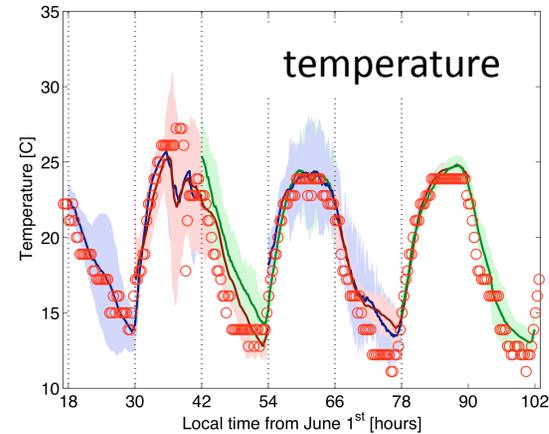

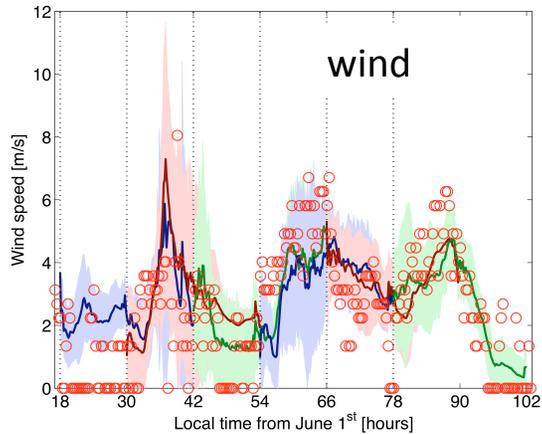

Wind power is difficult to predict

- Wind power measurements for Chicago
- Deterministic prediction; a new one started every 12 hours
- Forecast with uncertainty

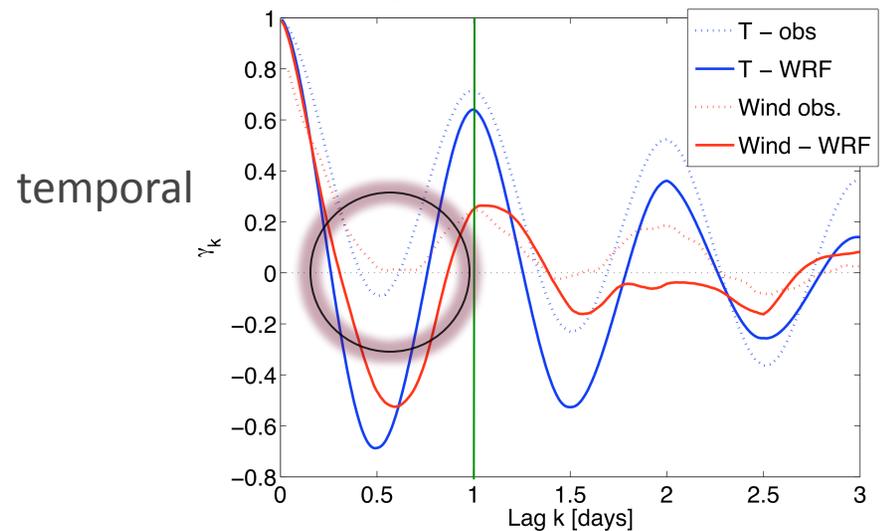

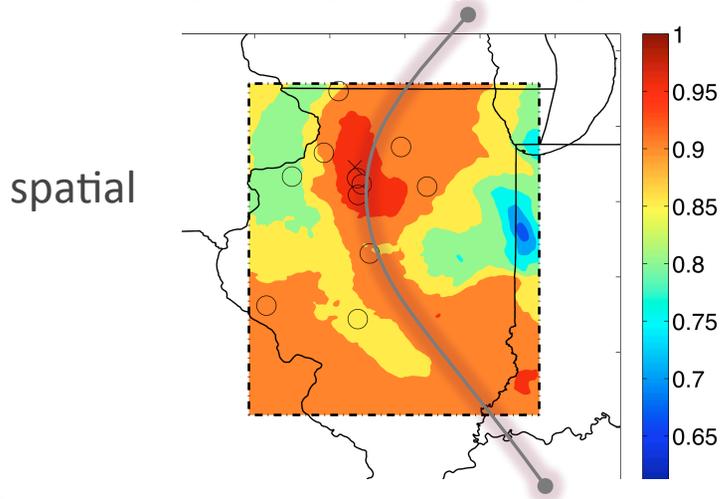

Validation of the wind/temperature forecast and uncertainty

- Wind/temperature validation of uncertainty estimates with real measurements

- Temporal [trends] and spatial [similar outcomes] correlations provide additional info

Optimization under Uncertainty by Stochastic Programming

Rolling Horizon Optimization

Benefits: Accommodate Forecasts, Constraint Handling, Financial Objectives, Complex Models

Deterministic

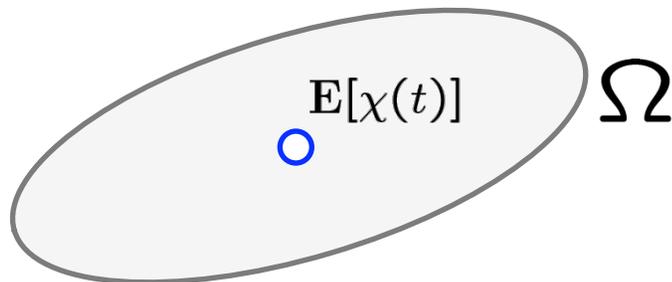

$$\min_{u(t)} \int_{t_\ell}^{t_\ell+N} \varphi(z(t), y(t), u(t), \mathbf{E}[\chi(t)]) dt$$

$$\frac{dz}{dt} = \mathbf{f}(z(t), y(t), u(t), \mathbf{E}[\chi(t)])$$

$$0 = \mathbf{g}(z(t), y(t), u(t), \mathbf{E}[\chi(t)])$$

$$0 \geq \mathbf{h}(z(t), y(t), u(t), \mathbf{E}[\chi(t)])$$

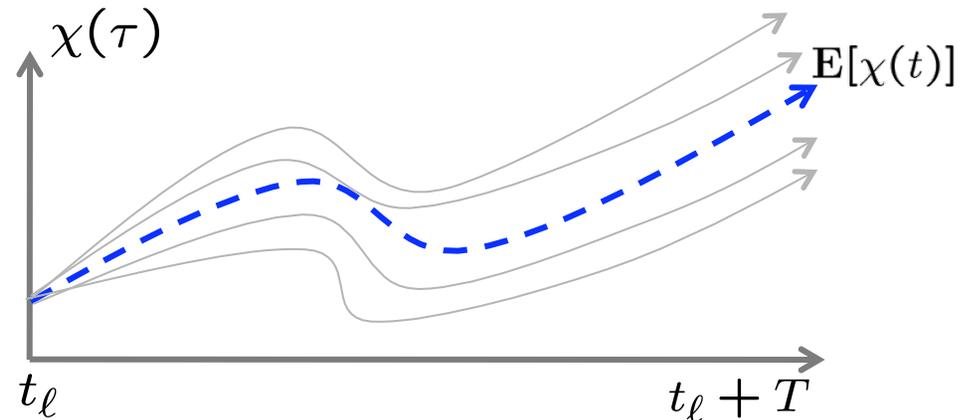

$$z(0) = x_\ell$$

Complexity (Solution Time)

1,000 – 10,000 Differential-Algebraic Equations

100-1000 Scenarios

Stochastic

$$\min_{u(t)} \mathbf{E}_{\chi(t) \in \Omega} \left[\int_{t_\ell}^{t_\ell+N} \varphi(z(t), y(t), u(t), \chi(t)) dt \right]$$

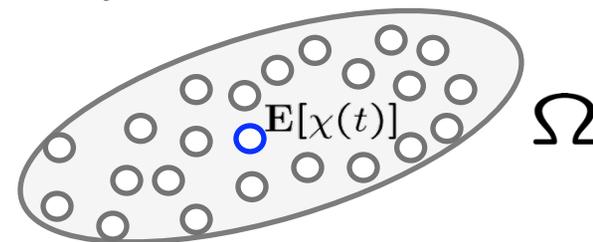

$$\frac{dz}{dt} = \mathbf{f}(z(t), y(t), u(t), \chi(t))$$

$$0 = \mathbf{g}(z(t), y(t), u(t), \chi(t))$$

$$0 \geq \mathbf{h}(z(t), y(t), u(t), \chi(t))$$

$$z(0) = x_\ell$$

$\forall \chi(t) \in \Omega$

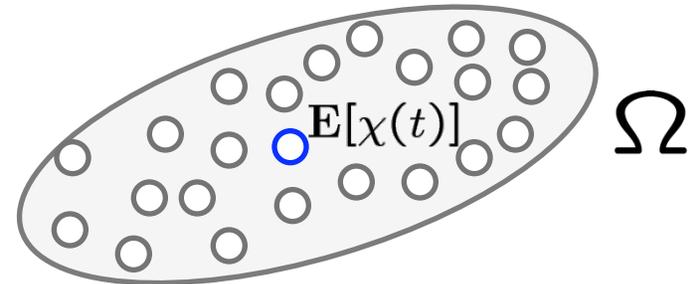

Stochastic Rolling Horizon Optimization

Solution Strategies

- **Dynamic Programming, Taylor Series:** Handling Constraints and Nonlinearity Cumbersome
- **Polynomial Chaos:** Dense Optimization, Multivariable Quadrature
- **Sample Average Approximation (SAA):** Sparse Optimization, Constraints, General Framework

$$\min_{u(t)} \mathbf{E}_{\chi(t) \in \Omega} \left[\int_{t_\ell}^{t_\ell+N} \varphi(z(t), y(t), u(t), \chi(t)) dt \right]$$

$$\left. \begin{aligned} \frac{dz}{dt} &= \mathbf{f}(z(t), y(t), u(t), \chi(t)) \\ 0 &= \mathbf{g}(z(t), y(t), u(t), \chi(t)) \\ 0 &\geq \mathbf{h}(z(t), y(t), u(t), \chi(t)) \\ z(0) &= x_\ell \end{aligned} \right\} \forall \chi(t) \in \Omega$$

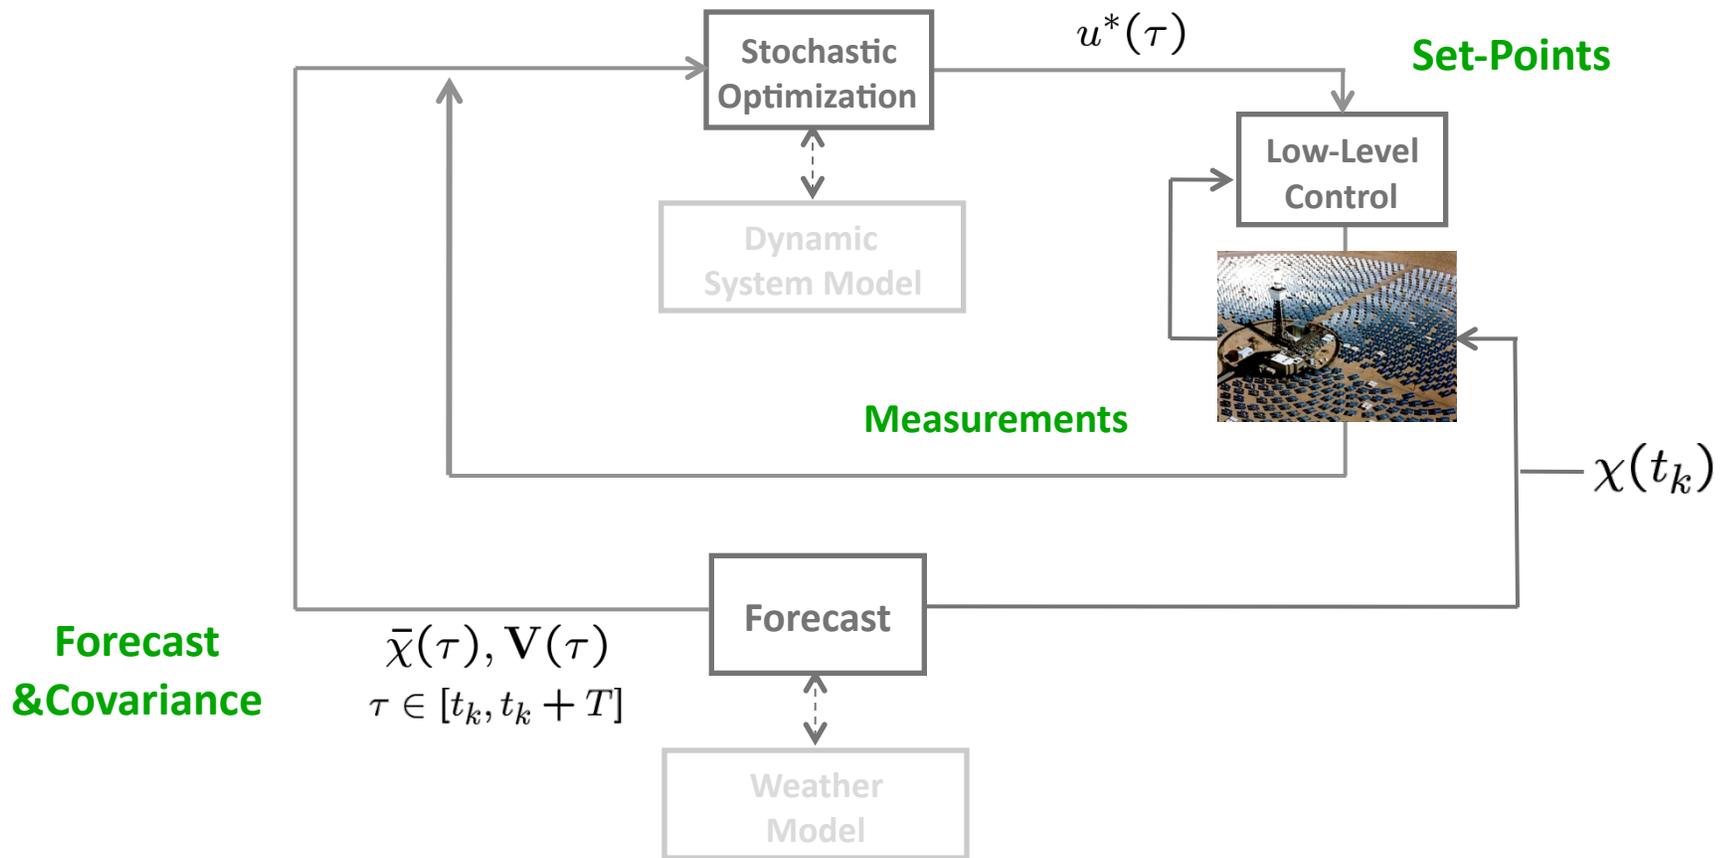

Nonlinear Programming: Exploit Fine and Coarse Structures at Linear Algebra Level

$$\begin{aligned} \min_{\mathbf{u}} \quad & \frac{1}{S} \sum_{k=1}^S \varphi(z_k, y_k, \mathbf{u}, \chi_k) \\ \text{s.t.} \quad & \mathbf{c}(z_k, y_k, \mathbf{u}, \chi_k) = 0 \\ & \mathbf{h}(z_k, y_k, \mathbf{u}, \chi_k) \leq 0 \\ & k = 1, \dots, S \end{aligned}$$

$$\begin{bmatrix} \mathbf{K}_1 & & & Q_1 \\ & \mathbf{K}_2 & & Q_2 \\ & & \dots & \vdots \\ & & & \mathbf{K}_S & Q_S \\ Q_1^T & Q_2^T & \dots & Q_S^T & D_{\mathbf{u}} \end{bmatrix} \begin{bmatrix} \Delta s_1 \\ \Delta s_2 \\ \vdots \\ \Delta s_S \\ \Delta \mathbf{u} \end{bmatrix} = - \begin{bmatrix} r_1 \\ r_2 \\ \vdots \\ r_S \\ r_{\mathbf{u}} \end{bmatrix}$$

Basic Operational Setting

Quantifying Uncertainty Key Enabler

Digression about the Suitability of Stochastic Programming for Energy Systems w Renewables

SAA Stochastic Programming Approximation.

$$\begin{aligned} \min_{\mathbf{u}} \quad & \frac{1}{S} \sum_{k=1}^S \varphi(z_k, y_k, \mathbf{u}, \chi_k) \\ \text{s.t.} \quad & \mathbf{c}(z_k, y_k, \mathbf{u}, \chi_k) = 0 \\ & \mathbf{h}(z_k, y_k, \mathbf{u}, \chi_k) \leq 0 \\ & k = 1, \dots, S \end{aligned}$$

- One weakness of stochastic programming is that it assumes a distribution is given. In most applications of interest, the distribution has to be modeled from data using some knowledge of the application.
- If the uncertainty originates in weather forecast, there is a strong empirical and theoretical basis to create the distribution, or, at least to sample from it.
- To our knowledge this is the first time even a moderately complex energy system was managed using stochastic programming with real and **operational** weather uncertainty.

Sequential Decision Making Under Uncertainty: Stochastic Dynamic Programming

- Stoc DP is the most distinguished framework, though rarely (ever ?) approached from HPC.
- Example: In Production and Inventory Planning:

– Recursive Cost at the beginning of stage t :

$$f_t(I, \omega_{1:(t-1)}) = \min_{\substack{\max(0, d_t - I) \leq x \\ \min(C, d_t + B - I)}} E_t \left[c_t(x, \omega_t) + f_{t+1}(I + x - d_t, \omega_{1:t}) \right]$$

- **Functional approximation in an T^*D ($D \sim 1000s$) dimensional space !!!** It suffers from the curse of dimensionality ... but so does sampling.
- Could HPC make inroads? We believe so but development cost restricts us to rolling horizon.

Applications

App 1: The operator's (ISO-IL) problem Unit commitment with wind power generation

[E.M. Constantinescu V. Zavala, M. Anitescu, M. Rocklin, S. Lee]

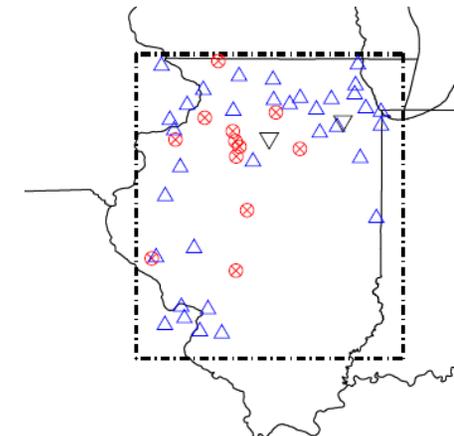

- Deterministic problem:

$$\begin{aligned}
 & \min_{p_{j,k}, \bar{p}_{j,k}, \dots} \sum_{j \in \mathcal{N}} \sum_{k \in \mathcal{T}} c_{j,k}^p + c_{j,k}^u + c_{j,k}^d \\
 & \text{s.t.} \quad \sum_{j \in \mathcal{N}} p_{j,k} + \sum_{j \in \mathcal{N}_{wind}} \mathbb{E} \{ p_{j,k}^{wind} \} = D_k \\
 & \quad \sum_{j \in \mathcal{N}} \bar{p}_{j,k} + \sum_{j \in \mathcal{N}_{wind}} \mathbb{E} \{ p_{j,k}^{wind} \} \geq D_k + R_k \\
 & \quad \dots
 \end{aligned}$$

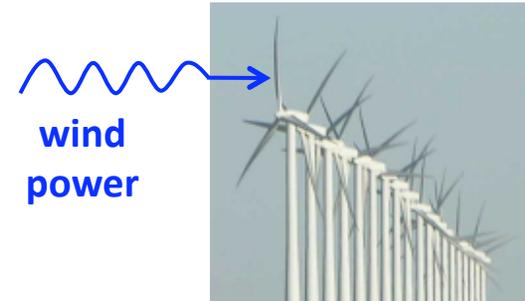

- Stochastic program formulation:

$$\begin{aligned}
 & \min_{p_{s,j,k}, \bar{p}_{s,j,k}, \dots} \frac{1}{N_S} \sum_{s \in \mathcal{S}} \left(\sum_{j \in \mathcal{N}} \sum_{k \in \mathcal{T}} c_{s,j,k}^p + c_{j,k}^u + c_{j,k}^d \right) \\
 & \text{s.t.} \quad \sum_{j \in \mathcal{N}} p_{s,j,k} + \sum_{j \in \mathcal{N}_{wind}} p_{s,j,k}^{wind} = D_k \\
 & \quad \sum_{j \in \mathcal{N}} \bar{p}_{s,j,k} + \sum_{j \in \mathcal{N}_{wind}} p_{s,j,k}^{wind} \geq D_k + R_k \\
 & \quad \dots
 \end{aligned}$$

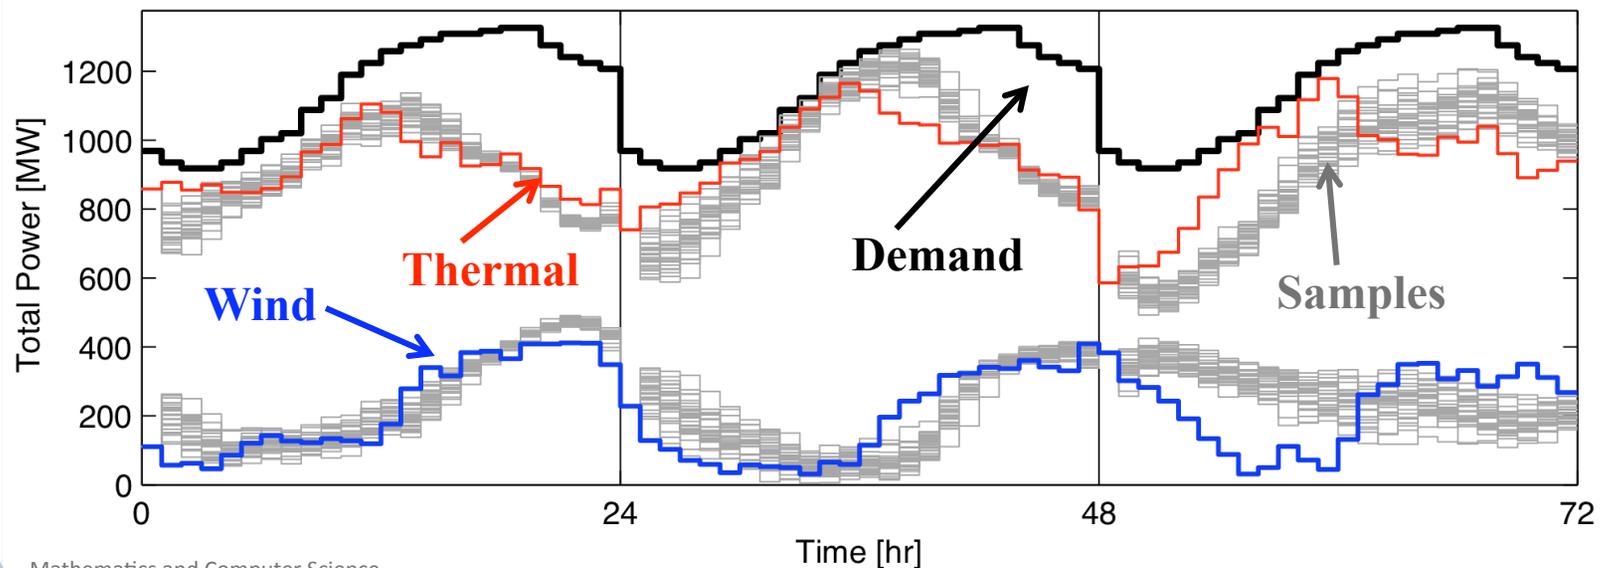

Wind power forecast and stochastic programming

- Unit commitment & energy dispatch with uncertain wind power generation for the State of Illinois, assuming 20% wind power penetration, using the same windfarm sites as the one existing today.

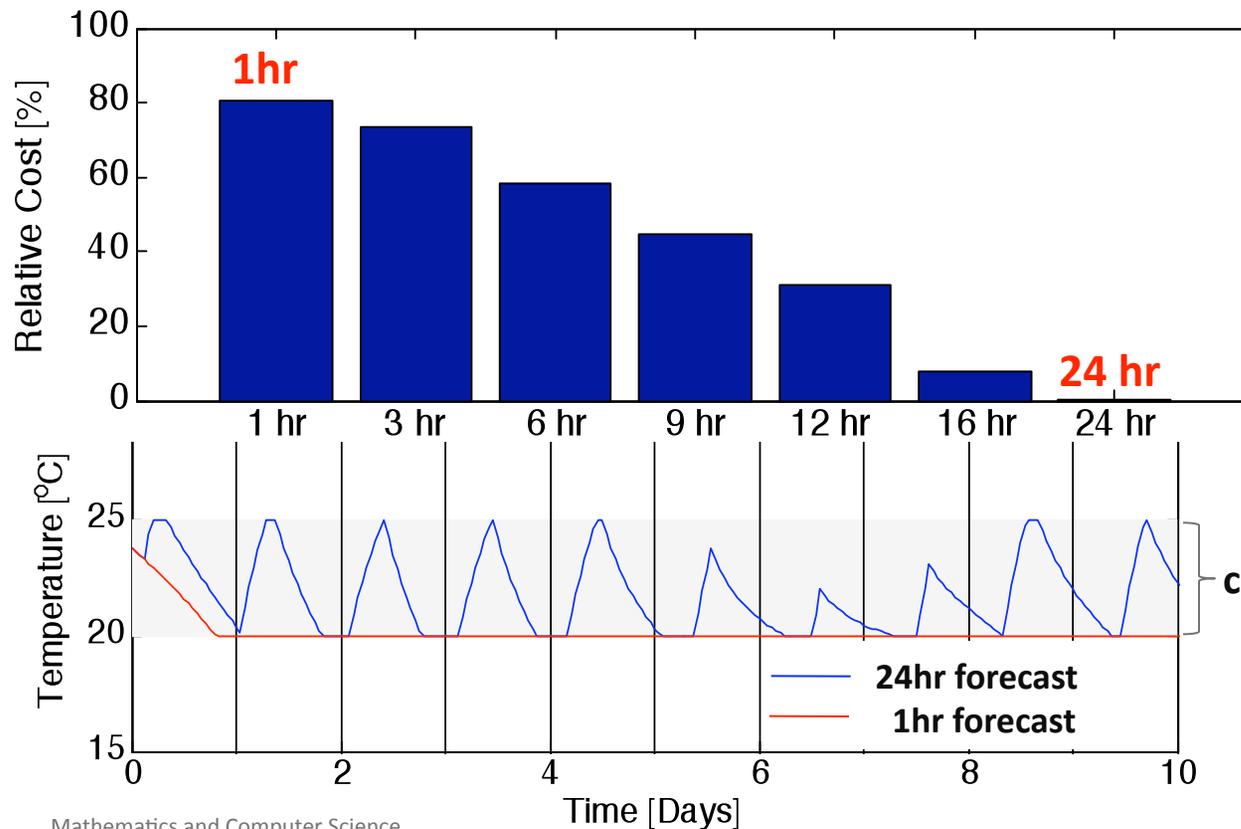

- Full integration with 10 thermal units to meet demands. Consider dynamics of start-up, shutdown, set-point changes
- The solution is only 1% more expensive than the one with exact information.

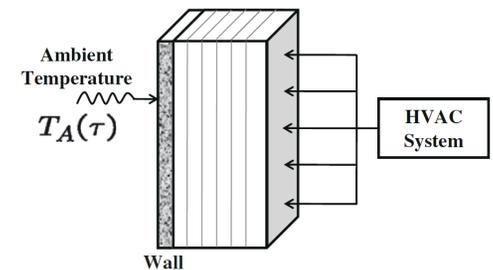

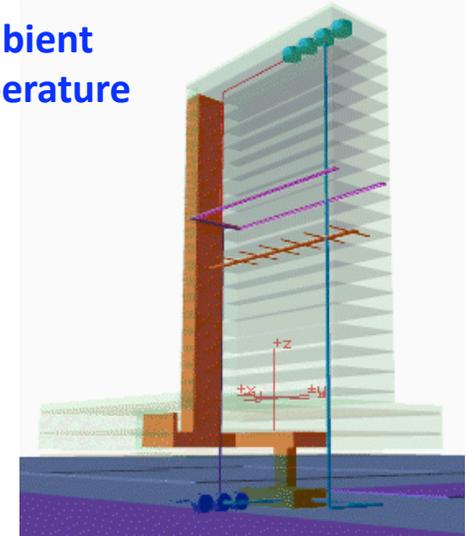

Ap2: Thermal management of building in Pittsburgh

- Minimize annual heating and cooling costs
- Time-varying electricity prices (peak/off-peak)
- Forecast with uncertainty leads to 20-80% cost reduction (insulation quality)

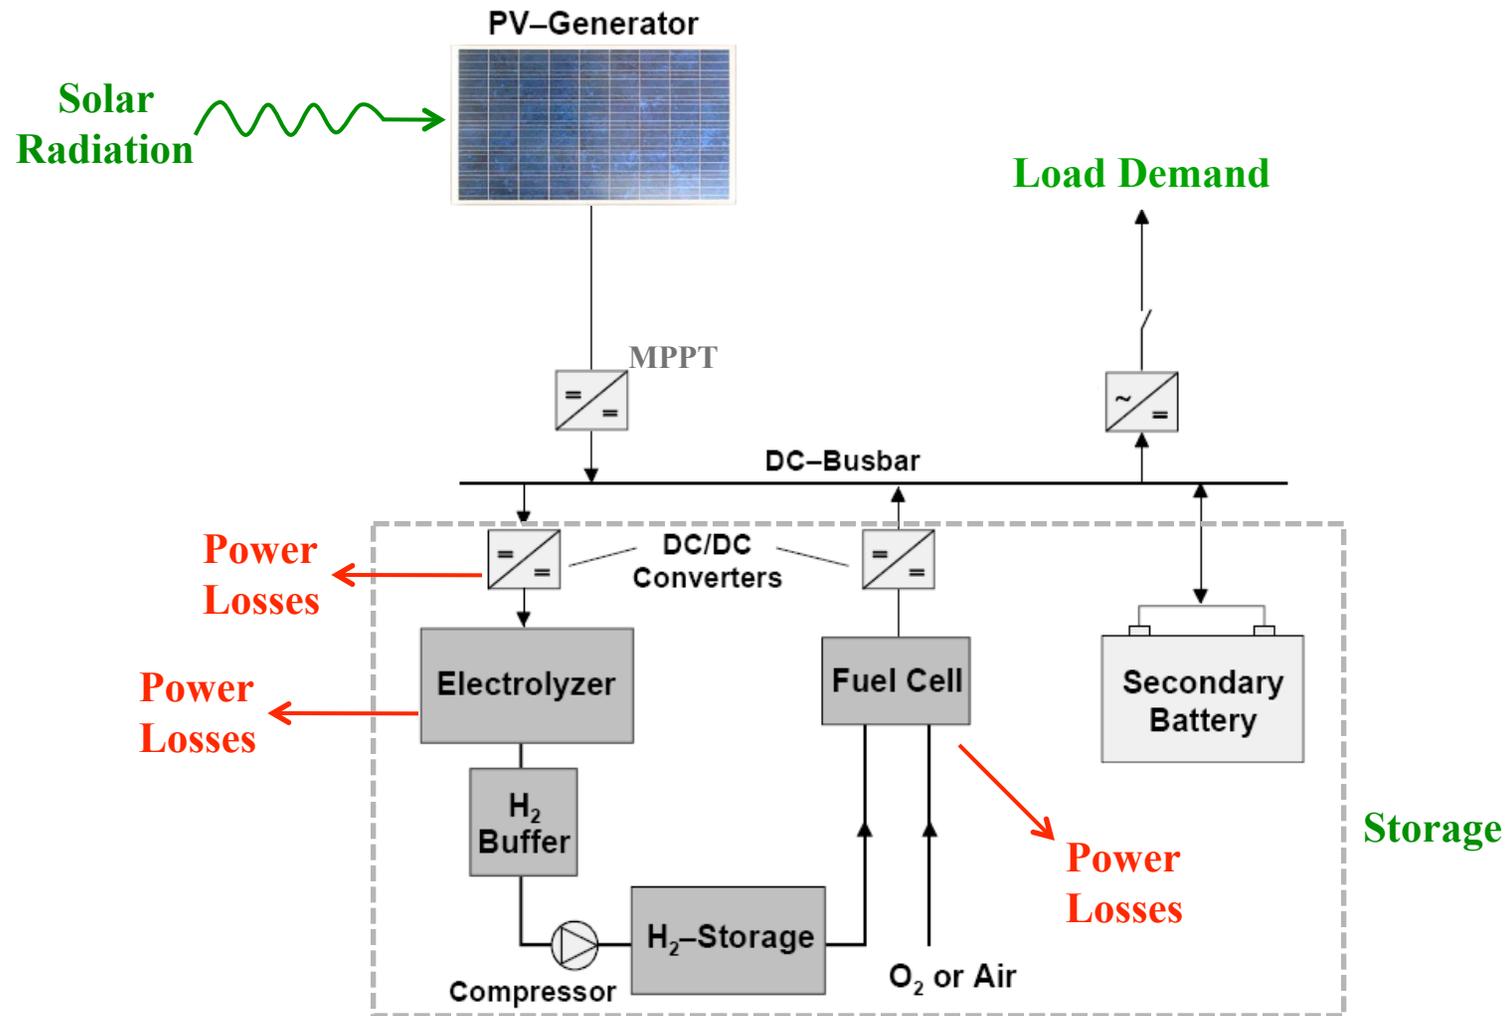

ambient temperature

comfort zone

[Zavala, Constantinescu, Krause, and Anitescu, 2009]

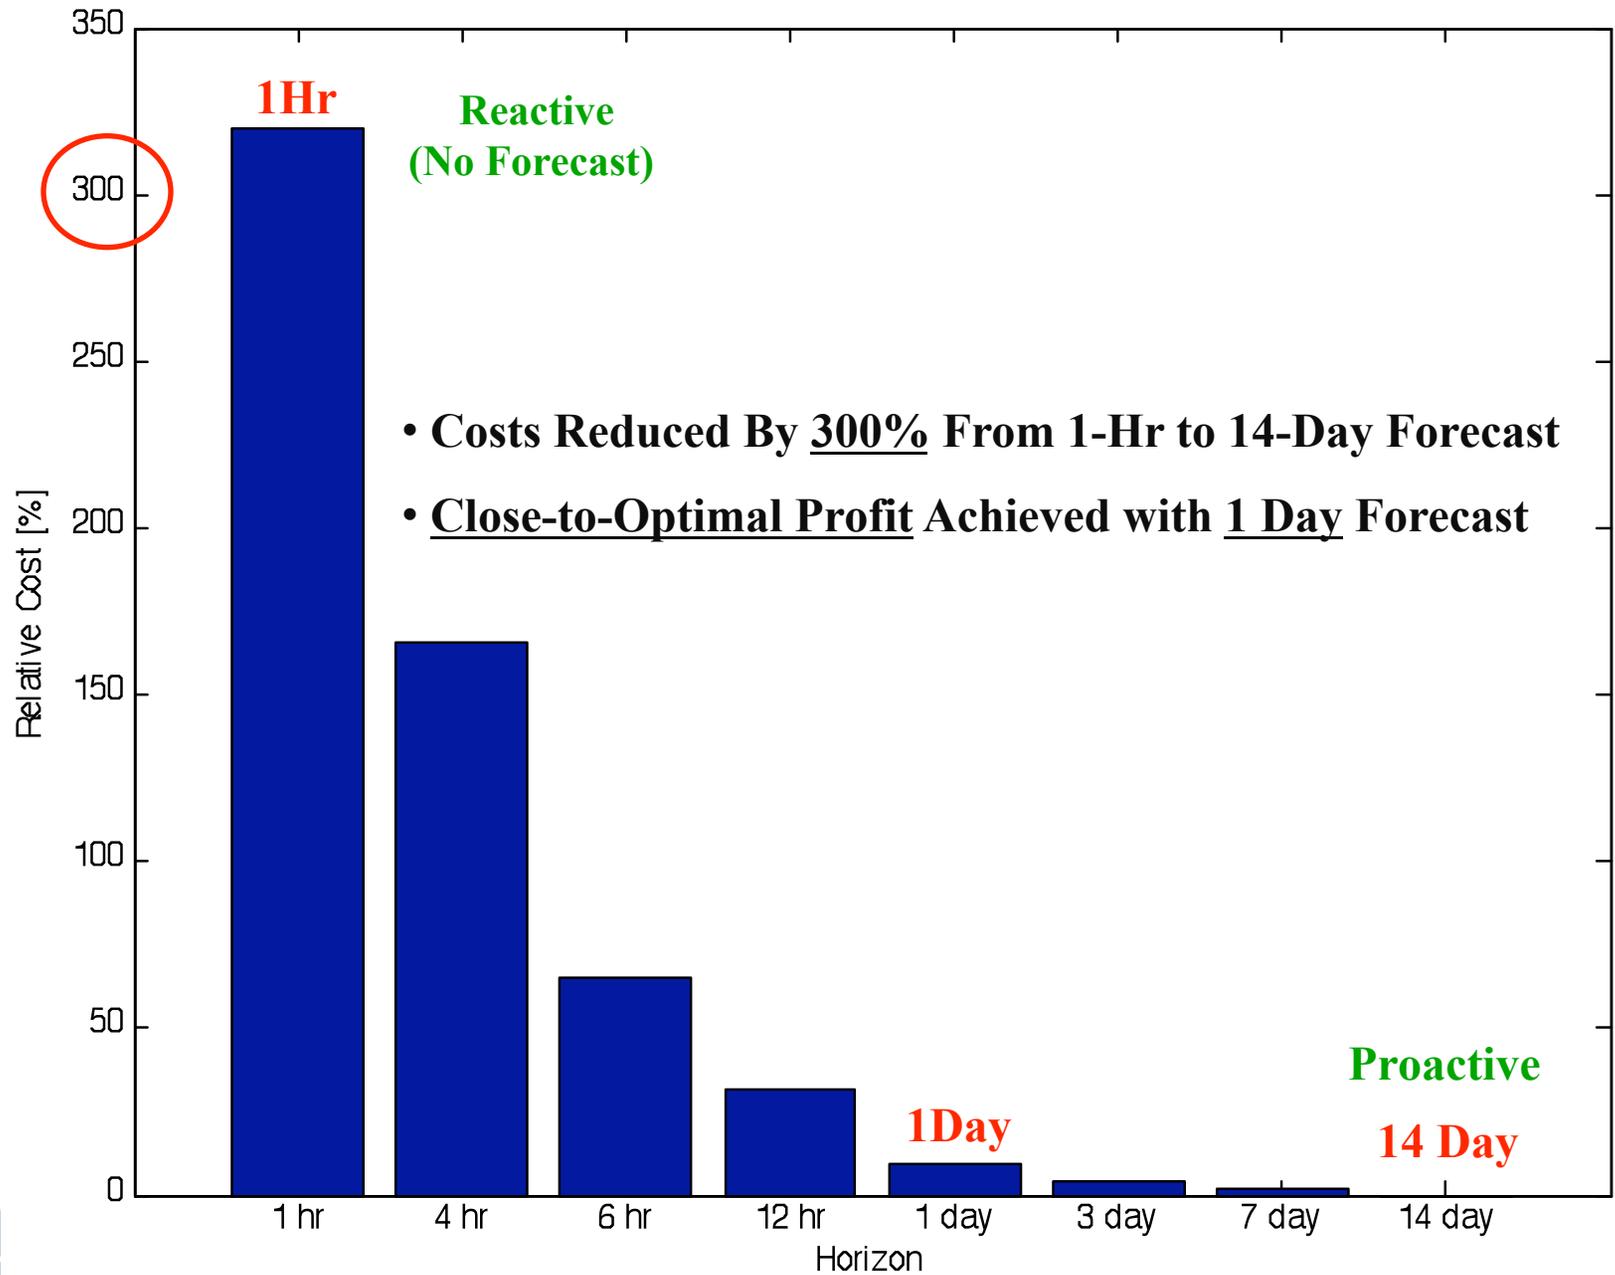

AP3: Hybrid Photovoltaic-H₂ System in Chicago, IL

• **Operating Costs Driven by Solar Radiation** *Ulleberg, 2004*

• **Performance Deteriorated by Power Losses**

Is it worth using Stochastic Programming and WRF? Or there are simple bypasses?

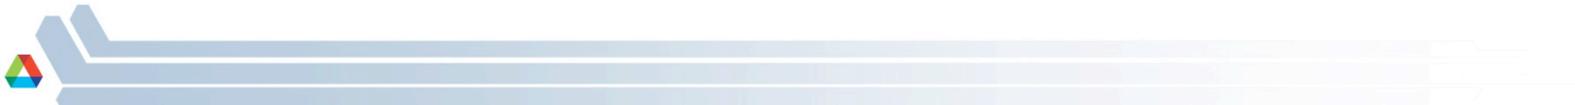

- The case for forecast seems clear. But how about
 - (Q1) Do I need Stochastic Programming and uncertainty? Maybe if I do deterministic programming on average it is sufficient.
 - (Q2) Do I need WRF to do it? Or can I get by with massaging historical data.
- We Present evidence of Yes on both counts.

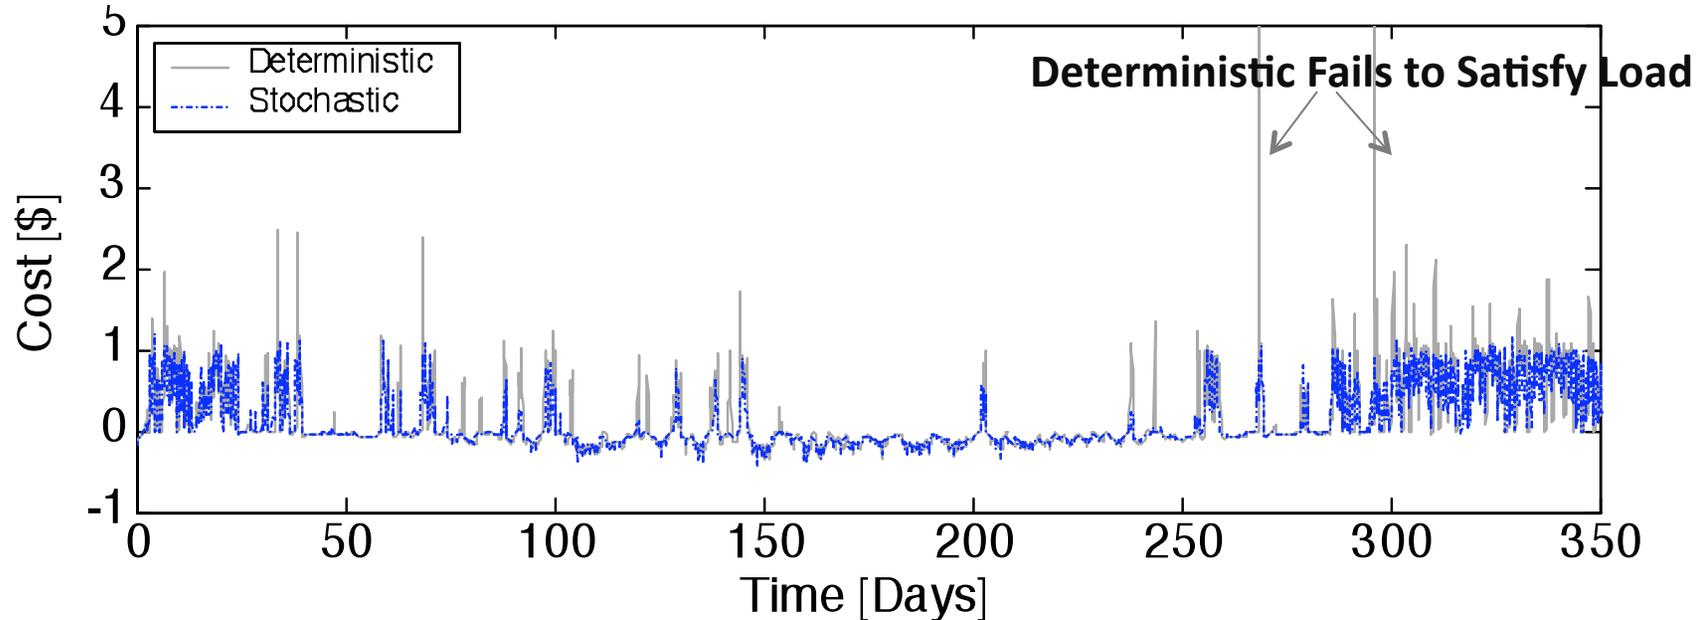

App 1: Regional SO commitment

- Deterministic strategy (Programming on average) cannot satisfy demand beyond 10% wind penetration (The reserves help some).
- Evidence for Q1=Yes.

App 3: Hybrid Photovoltaic-H₂ System

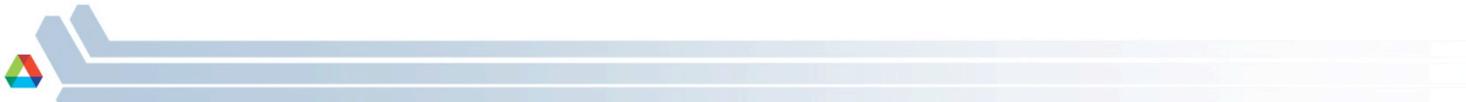

Load Satisfaction Deterministic (“Optimization on Mean”) vs. Stochastic

Therefore, the alternative to stochastic programming can turn out **infeasible !!**

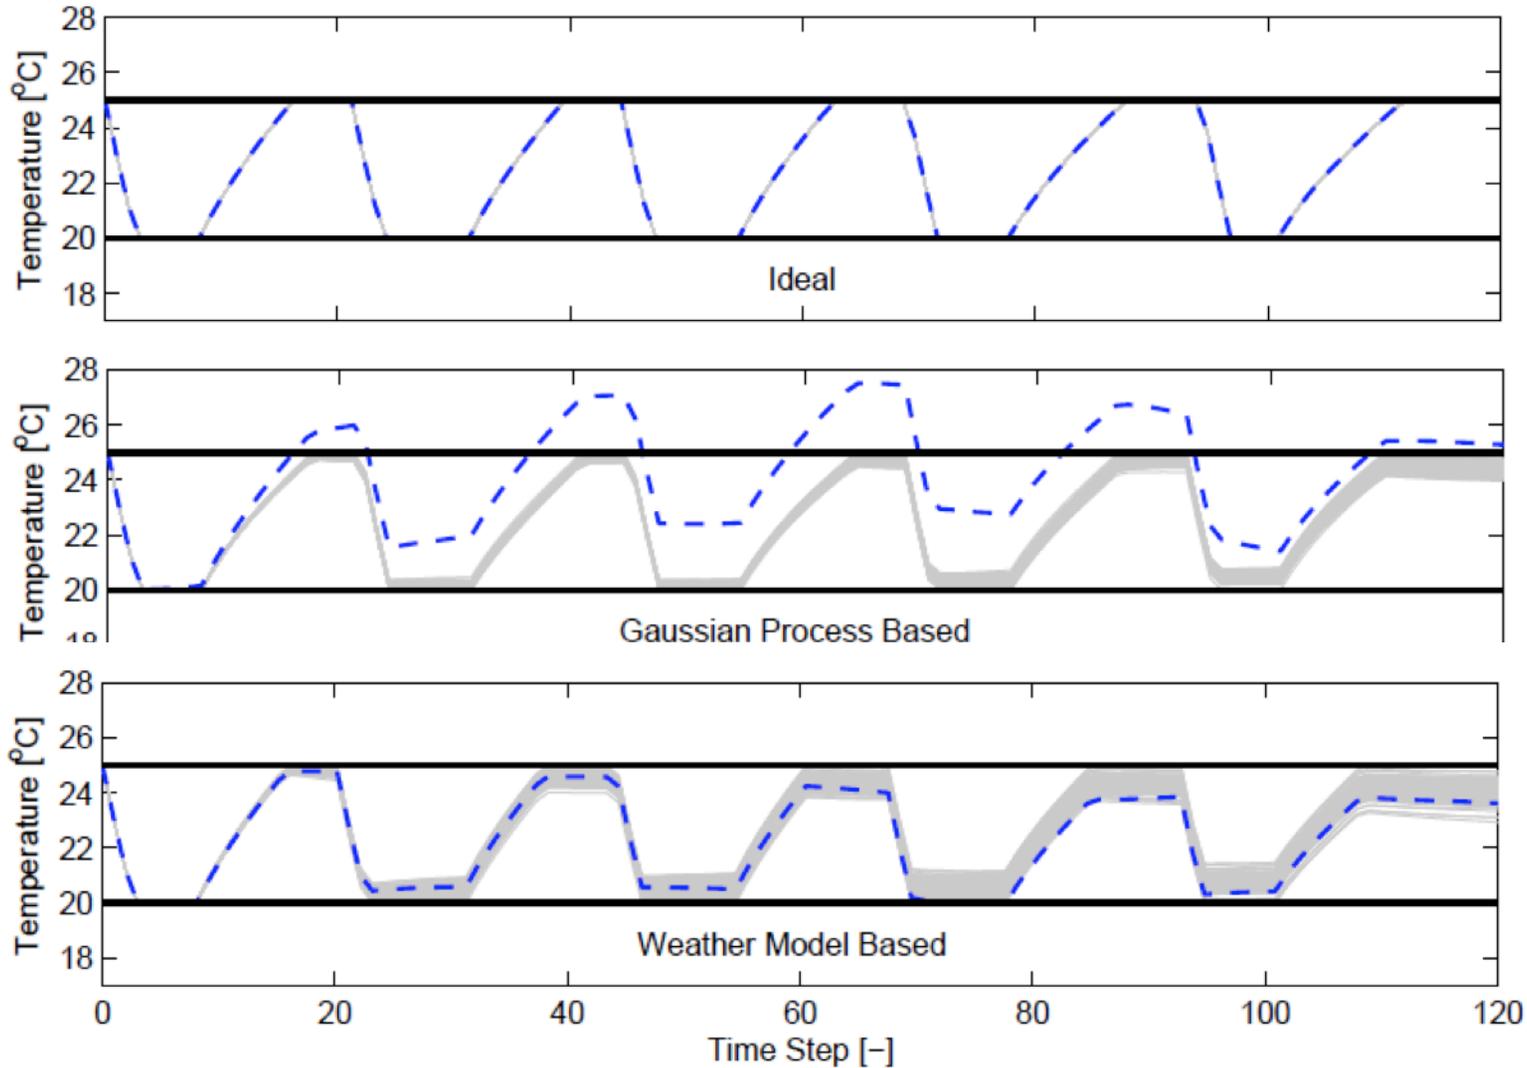

Handling Stochastic Effects Particularly Critical in Grid-Independent Systems where no recourse.

Evidence for Q1=Yes.

App2: Thermal Management of Building Systems

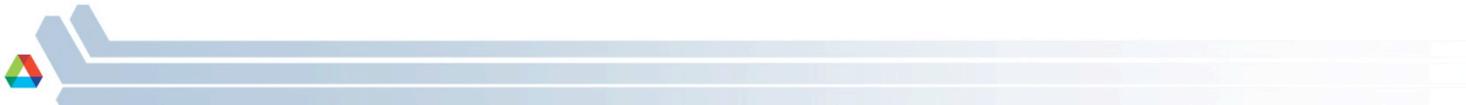

Performance Optimizer using WRF and GP Model Forecasts. Evidence for Q2=Yes.

Perfect
Forecast

Gaussian Process
(Data-only) Model

WRF
Model

Conclusions and Future Work

Integrative Study of Weather Forecast-Based Optimization

- Far as we know this is the first integrative study using validated WRF Model for an operational setting (1km, 1 day ahead, in 1hr).
- We showed that stochastic formulation matters hugely for satisfying constraints.
- Weather uncertainty is a hard, important, problem that data-only methods (such as GP) are unlikely to crack.
- We showed that weather forecast inclusions results in 20-80% cost reduction for rolling horizon.

Future and On-Going Work

- Better posterior sampling for weather forecast uncertainty.
- Dynamic Programming Formulations and comparisons with rolling horizon.
- High-resolution physics in WRF (feedback from wind farms?).
- Solving larger Stochastic MINLP problems.
- Modeling pricing and demand uncertainty.
- Real time cost-efficient techniques (buildings and PV).

Promise of HPC for Integrated Energy Systems Management

1. Predicting Weather Forecast with Uncertainty **Operationally**.

400K Processors would provide in one hour wall clock time 30 WRF Ensemble Members for the next 24 hours at 1 km resolution for the entire US. (Source: Extrapolation of Profiling)

2. Stochastic Dynamic Programming as a resource management strategy for Regional System Operators. ~ 10s of billions of dollars worth of activity per year. (Source: Our educated guess).
